

ABSTRACT

A management server stores information on necessary parts and a method for a task in individual memory sections
5 based on reception information received from a client.
Information on the parts needed for a task is transmitted to a transport vehicle terminal carried by a transport person in the case where the necessary parts are loaded on the transport vehicle. In the case where a worker in
10 charge has no further tasks that have been accepted, the worker calls up a work request list showing reception numbers, machine types and so forth from the management server. The worker selects workable items from the work request list and sends a command to update information in
15 the individual memory sections in the management server to the management server via a worker terminal.
